# Phased Array Feed Design

**Stuart Hay**  
**23 October 2009**

# Outline

- Why phased array feeds (PAFs) for radioastronomy?
- General features and issues of PAF approach
- Connected-array PAF approach in ASKAP

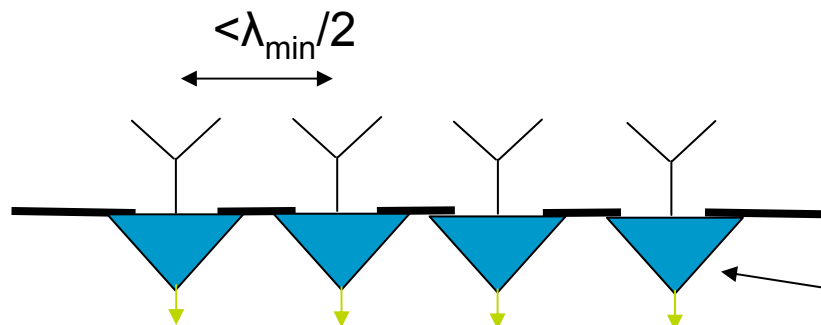

# Why PAFs?

- High sensitivity
- Wide field of view (FoV) (instantaneous and contiguous)
  - Survey speed  $(\eta_{\text{ap}} A_{\text{phy}} / T_{\text{sys}})^2 \times \Omega_{\text{FoV}}$
  - Possibilities for discovery (eg transient phenomena)
- Large frequency range (0.7-1.8GHz)

# PAFs in general

Concentrator (optics)

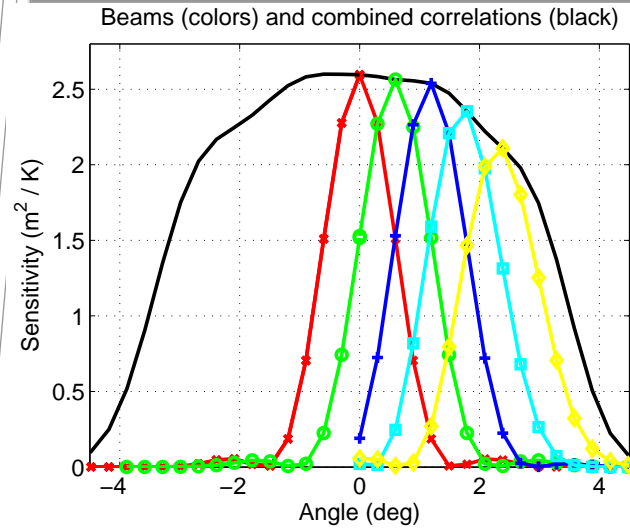

Beamformer (digital)

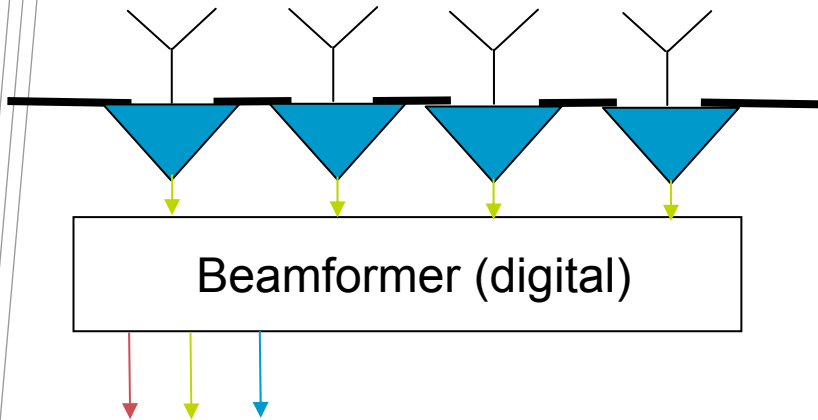

Low-noise amplifier (LNA)  
+ Digital conversion  
+ Polyphase filter

Beams (weighted sums of inputs)

# PAFs vs existing multibeam feeds

$< \lambda_{\min} / 2$

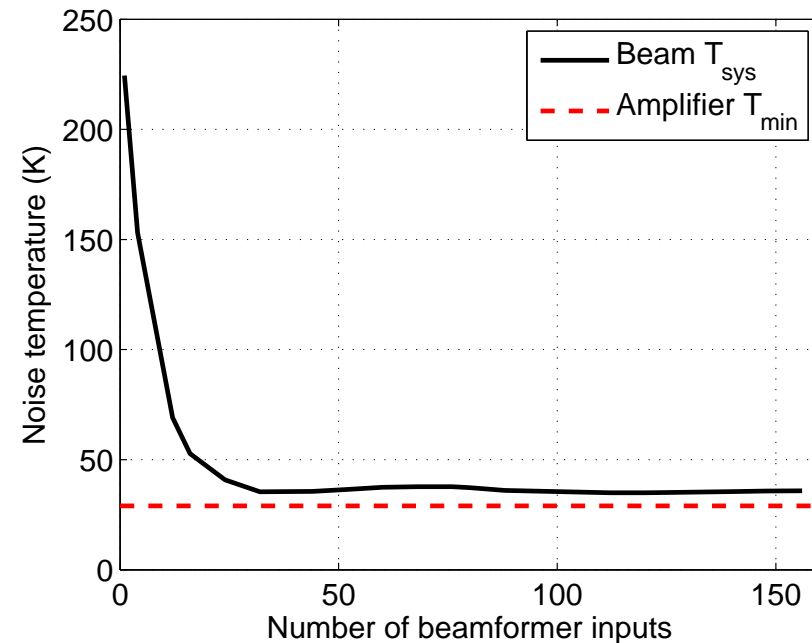

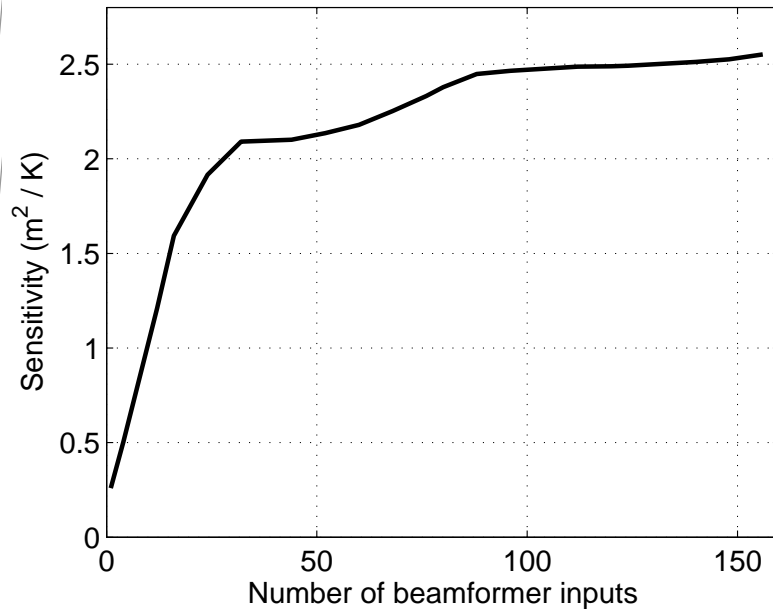

$> \lambda_{\max} / 2$

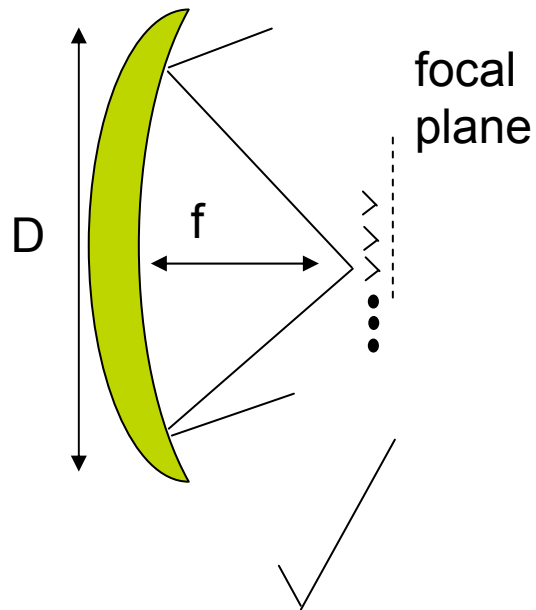

- PAF gives complete high-sensitivity sampling of FoV

# PAFs vs existing multibeam feeds

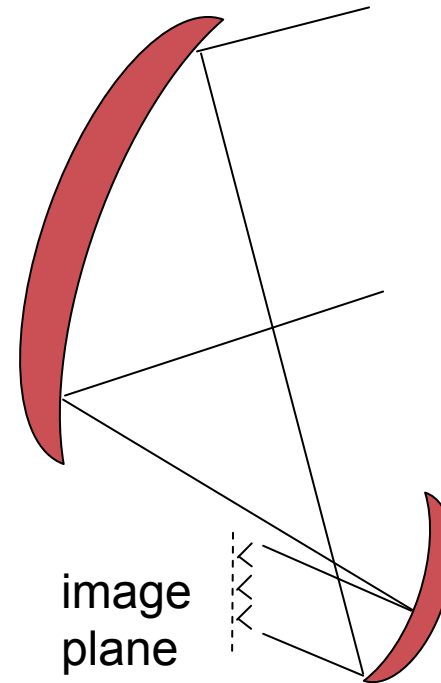

- PAF has significant mutual coupling effects
  - However beam  $T_{\text{sys}} \rightarrow$  amplifier  $T_{\text{min}}$  with optimum (active) noise matching of array/amplifiers and optimum beamforming

# PAF optics - focal vs image plane

- #elements  $\propto (f/D)^2$  and area of FoV
- Compromise between  $f/D$  and  $\eta$
- Can beamform subsets of elements
- Can expand FoV by adding more elements (upgrade path)

- #elements determined by magnification
- All elements must be beamformed for good  $\eta$
- FoV limited by subreflector size

# PAF optics - beam stability

- Beam stability with respect to the astronomical sources is required for high dynamic range image formation
- Possibly solutions in clear-aperture (offset-fed) optics and electronic beam rotation through beamformer weights
- ASKAP will use a 3-axis antenna design

# PAF optics - beam stability

# PAF/LNA issues

- Uncooled LNAs with  $T_{\min}$  in 20-40K range over 0.5-2GHz have been developed
  - $T_{\text{sys}}/\eta_{\text{ap}} < 70\text{K}$  realistic target that would make PAFs competitive
- Cooling PAFs is not straightforward
  - Many coupled elements distributed over large area
  - However should be further considered
- Differential LNAs and LNAs with  $>50\Omega$  noise-match impedance are desired for some PAF designs
  - Reduce balun loss
  - Minimize LNA  $T_{\min}$
  - LNA modelling and measurements require further work

# Connected-array approach to PAF

- Broaden PAF investigation
  - Previously focussed on Vivaldi (ASTRON and DRAO)
- Planar connected arrays
  - Alternative viewpoint emphasizing mutual coupling
  - Possible advantages of planar and low-profile structure
    - Cost
    - Loss
    - Integration
    - Noise coupling?
    - Cooling?
    - Other?

Prototype connected-patch FPA

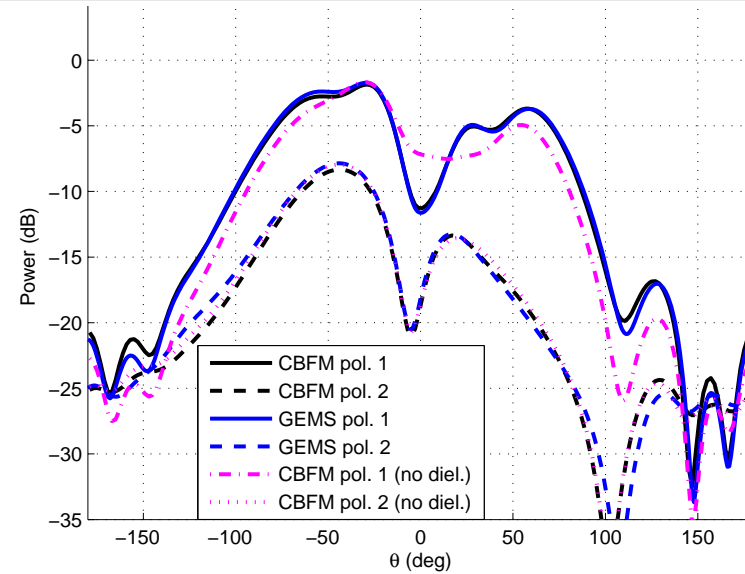

# Connected-array approach

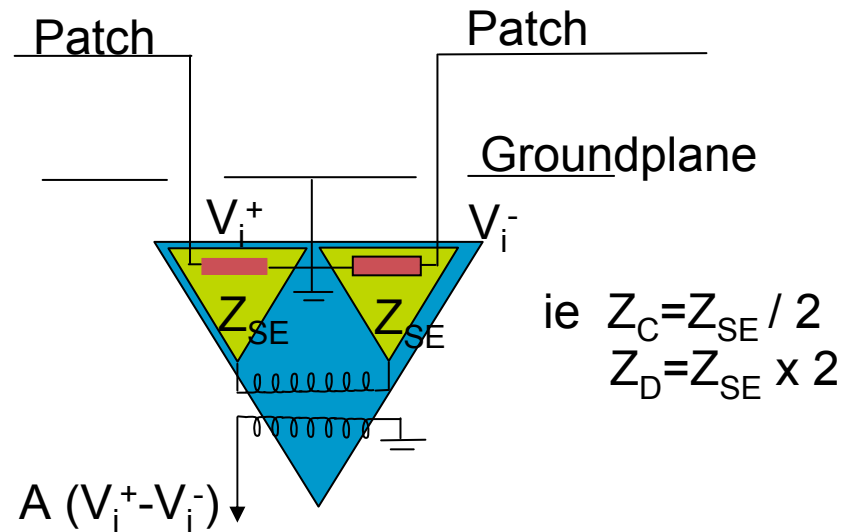

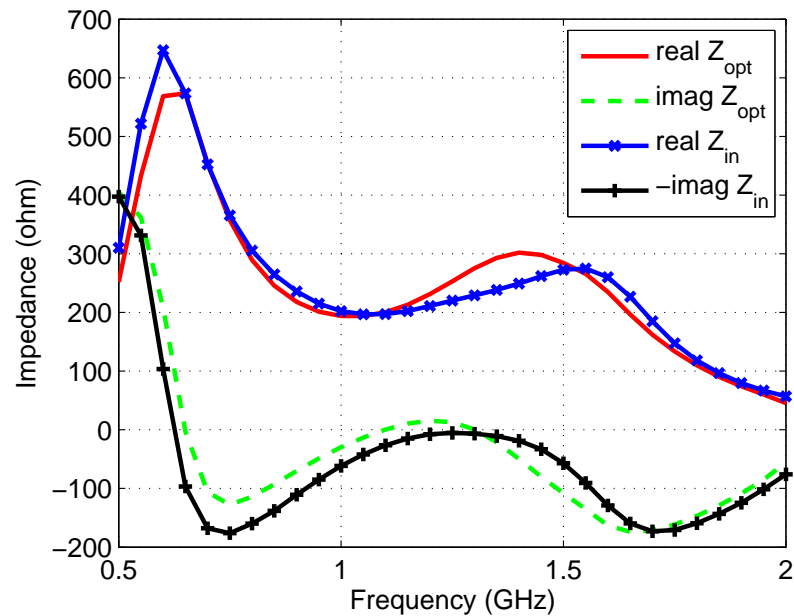

- Current continuity enhances bandwidth (element spacing  $< \lambda/2$ )
- Target 0.7-1.8GHz frequency range
- 9x10x2 elements for  $\sim 30$  sq deg FoV
- D=12m front-fed reflector with  $f/D=0.5$

# Approach to the design

- Develop modelling capability
  - Electromagnetic modelling of array
  - Electronic modelling of LNA
- Numerical and experimental investigations of prototype
  - Resonances and matching to LNA
  - Radiation pattern in chamber
  - Parkes 12m testbed
- Optimize larger design for ASKAP

# Connected-array matching

- $Z_{diff} \sim 377\Omega$  LNA optimum noise-match impedance in mutually coupled array environment
- Lower  $Z_{diff}$  modifications to array will lessen sensitivity to parasitics
